Q1 I have observed a major difference with waitpid() function if there is no waitpid function the program takes only a part of the program and outputs the screen, if there is waitpid then it outputs the complete txt file to the screen.

Q2 In this program, after giving a line for every newline character converts every lowercase character to uppercase stores it the buffer and outputs to stdout; from there the child process takes each line, adds a newline to it and then it outputs to the screen.
